**Theme: Real estate market analysis**

---

<sup>1</sup> This research was funded by the National Science Council, Taiwan (NSC 98-2410-H-006-093-SSS)

## 1 Introduction

The Real Estate Cycle Indicators<sup>2</sup> along with the Land & Housing Value Index as shown in Figure 1 and 2 suggest that Taiwan's real estate market had been declined since the second quarter of 2007 and became in deep recession since the third quarter of 2008. On the other hand, the real estate market in Kaohsiung remains prosperous due to the fact that lots of transportation related infrastructure projects had been completed as shown in Figure 3. For example, Taiwan High Speed Rail was inaugurated in January 2007 and two mass transit lines of Kaohsiung Rapid Transit System<sup>3</sup> (KRTS) were completed in September 2008. And two transit related projects, i.e., a circular light rail transit line and the underground section of Taiwan Railways, are under construction and planned to be completed in the next few years. With the improvement of transportation infrastructure and the provision of employment opportunities from these projects, the real estate market in Kaohsiung has been fueled and energized in the past few years. Nevertheless, properties around MRT stations as shown Table 1 reveal no sign of significant decline during the period of recession. From Table 1 we also learn that there exists substantial price premium for better accessibility to MRT stations. And we want to use the assessment of price premium as initiatives to promote transit-oriented development in Kaohsiung.

To analyze the factors affecting property prices, we apply hedonic price method to estimate model parameters using the transition data of Kaohsiung metropolitan area<sup>4</sup> provided by the Ministry of the Interior. The variables of our models include attributes related to the property, the neighborhood, and the accessibility measured by the distances to transportation terminals. The functional forms of our models consist of linear, semi-log linear, log-linear, and Box-Cox transformation. By the comparison of hedonic functions of 2007 and 2008, we conclude that the

---

<sup>2</sup> The indicators published by Architecture and Building Research Institute, Ministry of the Interior, consist of GDP, monetary supply, index of construction stocks, bank loans to property mortgage, and CPI.

<sup>3</sup> KRTS consists of two lines, i.e., Red Line and Orange Line, with the total length of 40.4 km and 36 stations. The system was constructed under the Build-Operate-Transfer (BOT) method. As of July 2008, the average daily ridership of the system is 108,957 passengers.

<sup>4</sup> The metropolitan area includes the majority of cities and townships in Kaohsiung County and part of Pintung County. The total population of Kaohsiung metropolitan area, as of 09/30/2008, is around 2,775,000.

decline of commercial property was approximately six percent in the third quarter and ten percent in the fourth quarter of 2008. On the other hand, a price premium of between eleven and thirty percent for property near KMRT stations was retained after the onset of the crisis. The conclusion is that the crisis did not affect the relative price premium for good transit accessibility.

## 2 Hedonic Prices

Hedonic price theory is associated with the introduction of the term in a paper by Sherwin Rosen (1974), using ideas that had already been introduced by a number of economists in the 1960s

(see, for example, Lancaster 1966). Rosen uses a utility-maximizing approach to derive implicit attribute prices for multi-attribute goods under conditions of perfect competition, where each attribute has a unique implicit price in equilibrium. Perfect competition, however, rests on assumptions of perfect information, which is not normally approximated in markets for housing or other real estate markets.

Perfect competition is however not a necessary assumption for empirical hedonic price studies. Barzel (1989) approaches multi-attribute goods in a more dynamic way, by building on the insights of property rights theorists such as Demsetz (1967). Webster and Lai (2003) extend Barzel's theory to spatial economics in a way that explicitly takes dynamic processes and imperfect information into account. From such a dynamic standpoint, empirical hedonic price models do not produce stable estimates of equilibrium prices, but rather snapshots of transitional conditions. For example, a discovery of two centers with a metropolitan impact does not necessarily invalidate the common monocentric assumption; it could be a transitional stage where a declining and an emerging center both impact the willingness to pay of market participants for a finite time period – a reflection of asymmetric and imperfect information among buyers and sellers.

In general, hedonic price models aim at disentangling the attributes of a good from one another for the purpose of estimating implicit prices. In housing models, the price or rent is a function of various attributes, typically divided into structural and location attributes. Location attributes can be further subdivided into general accessibility and localized neighborhood effects.

Regression techniques make it possible to estimate the implicit price for each attribute. Linear models are usually avoided, since the assumption of constant marginal implicit prices is untenable unless there are constant returns to scale in production or costless repackaging of two or more bundles. The most common non-linear models include log-linear, semi-log, and Box-Cox-transformed functions. The log-linear and semi-log functions are pre-specified functions, while Box-Cox functions uses an iterative procedure that maximizes the log-likelihood of the function within a pre-specified family of functions. Such maximization ensures a more desirable

distribution of the error term than with less flexible estimation techniques.

In this study, we use the log-linear functional form, which is both compatible with the underlying economic theory and relatively simple. The log-linear function has the additional interpretive advantage that the estimated coefficients correspond to average attribute elasticities. All pre-specified functional forms – including the log-linear function – has the advantage of allowing direct comparisons of quantitative attribute effects across markets.

On the other hand, it is often advisable to compare the results of different functional forms in order to identify non-robust estimates. For this reason, we estimated simple both-side Box-Cox functions for all models. The Box-Cox functions generally exhibited higher coefficients of determination and closer-to-normal distributions of residuals than the corresponding log-linear functions in all cases, except for the commercial data of the 2008 model. Indeed, the both-side model converged with  $\lambda = 0.07$ , which is virtually identical with the log-linear model (defined as  $\lambda = 0$ ).

### **3 Transit / Rail Accessibility and House Prices**

There are many studies of the effect of accessibility on housing development analyzing local transit networks. Rodriguez and Mojica (2009) have estimated a before and after hedonic model to determine the property value impacts on properties already served by the transit system caused by extensions to Bogota's bus rapid transit system. They used asking prices of residential properties belonging to an intervention area (N = 1407 before, 1570 after) or a control area (N = 267 before, 732 after) and offered for sale between 2001 and 2006 are used to determine capitalization of the enhanced regional access provided by the extension. They found that properties offered during the year the extension was inaugurated and in subsequent years have asking prices that are between 13% and 14% higher than prices for properties in the control area, after adjusting for structural, neighborhood and regional accessibility characteristics of each property.

Bae etc (2003) analyzed the impact of Seoul's subway Line 5 on residential property values by using a hedonic pricing model. Their model shows that distance from a Line 5 subway station had a statistically significant effect on residential prices only prior to the line's opening. This is consistent with the anticipatory effect observed in other studies. Moreover, accessibility to transit had, in general, less of an impact on house prices than other variables such as the size of the unit, the quality of the school district, proximity to the high-status Kangnam subcenter, and possibly accessibility to recreational resources.

Armstrong and Rodriguez (2006) analyze a slightly more extensive rail network than in most hedonic studies. They estimated accessibility benefits of rail services in eastern Massachusetts, including multimodal accessibility to commuter rail stations and distance from the rail right-of-way. The results were inconclusive, except that proximity to commuter rail right-of-way produced a significant negative effect on property values, which probably reflects negative externalities such as noise.

Bowes and Ihlanfeldt (2001) suggest that railroad station accessibility should affect property values since such access reduces commuting costs. This should help attract retail activity from localities further away from stations, other things being equal. Possibly countering these positive effects are negative externalities such as noise and better access for criminals. Their results - from Georgia in the United States - suggest that stations that are located sufficiently far away from the urban core tend to attract new residential development.

Studies of the regional enlargement of the Stockholm region in Sweden show that the radius of the price-distance gradient increased as a result of improved rail accessibility. Residential property prices in Uppsala could be partly explained by their time distance from downtown Stockholm after the introduction of a frequent 45-minute commuter train service with discounted fares for daily commuters (Andersson and Andersson, 2008).

With sufficiently good information flows, improved accessibility will be capitalized in land values in conjunction with the initial investment decision. The normal case is however imperfectly

informed markets, due to uncertainties regarding the credibility of decisions as well as future impacts of investments on the economy as a whole. The overall effect is therefore likely to be gradually incorporated into house prices, with distinct price effects that correspond to the sequence of relevant events: station location decisions; the commencement of construction; the opening of the line; and the cumulative experience from consuming transportation services. The first three effects should have been fully incorporated in the land value observations that we analyze in this paper, while the service experience component may have been capitalized in land values to a limited extent.

#### **4 Descriptions of the Data and Estimation Results**

The observations on transaction prices and structural characteristics were obtained from the Department of Land Administration of the central government, and cover all 2,137 and 2,490 residential property sales and 393 and 381 commercial property sales that were recorded in the metropolitan areas in 2007 and 2008, respectively. All the sale prices were adjusted to 2006 constant dollars. The education data are for 2004 and were obtained from the Ministry of Finance. The neighborhoods correspond to districts in the core cities and to townships in the rest of the metropolitan areas. A suggested income variable was unfortunately unavailable for districts, but the correlation between average income and the percentage of residents with at least two years of college education is very high in districts and suburban townships, so the education variable is in effect also a proxy for income. The distance measurements are proxies for house-specific access to the MRT and HSR station, the Kaohsiung Internal Airport, the city center, and major shopping halls, respectively. The distance data correspond to the shortest route for motor vehicles according to a popular GIS program that covers the entire road network of Taiwan; *PaPaGo R12*.

The neighborhood attributes “commercial zone” and “residential zone” refer to Taiwanese zoning regulations, which are more flexible than in many other jurisdictions. Taiwan’s cities have retained a mixed-use character since “residential zones” allow commercial use on the first and

second floors of apartment houses and townhouses. “Commercial zones” allow for some residential use on higher floors. For example, downtown residential zones are often used for high-rise apartment blocks with high-value commercial use such as banks and luxury retailing on the first two floors. Moreover, land use regulations tend to be somewhat haphazardly enforced compared with European or North American cities (Bernstein, 2007).

The hedonic analysis makes use of sales prices rather than rents, which accounts for most transactions involving residential property. In addition, sales prices reflect expectations of future developments, and should therefore - unlike rents - reflect potential long-term future benefits of new or planned infrastructure investments. Table 2 is a list of all variables which specifies measurement units as well as the abbreviations that are used in estimation. Table 3 gives the means and standard deviations of the original untransformed variables. Table 4 shows the estimation results of the log-linear functions for residential and commercial property while Table 5 gives the estimation results of the Box-Cox transformation with significant parameters (we choose the absolute t value greater than 1 as the level of significance). Meanwhile, Table 4 excludes all quarter-specific constant in the 2007 apartment model due to the fact that there were only two transaction records for the first three quarters while Table 5 excludes all apartment models because Box-Cox approach did not provide robust estimations of model parameters. For the remaining significant variables, Table 4 and 5 also show that all the structural, neighborhood and accessibility measures are with the correct signs. And the data of 2008 provides better goodness-of-fit for both the residential and commercial models.

We also learn that all the ups and downs of housing prices as predicted by the quarter-specific constants are quite consistent with Kaohsiung Housing Index as shown in Figure 2. But the percentages of changes in property transition prices are small in comparison to the Housing and Land Value Indices. In other words, it is fair to address the statement that the global financial crisis only affects the local market in a minor way.

Another interesting finding is that the distance to HSR station has a positive effect for commercial properties in the 2007 model, which is the only positive HSR coefficient in our study,

but it becomes a negative effect in the 2008 model. There are quite a few reasons to explain the contradiction. First, HSR station become more accessible after the MRT lines was completed in 2008. Second, the station is not attractive for commercial activities in 2007 due to the fact that it is also in the vicinity of a highly polluted industrial center, but the major facility of the industry is scheduled to be relocated within few years. And the last reason is that a major shopping hall is scheduled to be built adjacent to the station in the near future.

Nevertheless, the distance to Kaohsiung main train station exhibits very significant negative effect on commercial properties in the 2007 model while insignificant positive effect in the 2008 model. The contradictory may rise from the fact that the benefit of accessibility improvement provided by MRT for the main train station is overshadowed by the inconvenience of a newly constructed underground railway project which will not be completed within five years.

It is no surprise that the hedonic price model exhibits significant effects of transit accessibility on property prices. In fact, it is the second most significant factors in the category of accessibility attributes. For residential properties, the elasticity of distance to CBD is about 13% to 29%, while the elasticity of distance to a MRT station ranges from 3% to 7%. As for commercial properties, the elasticity of distance to CBD is between 11% and 13% while the elasticity of distance to a MRT station ranges from 9% to 11%.

Although global financial crisis has minor effects on the local housing market, as suggested by the Housing Value Index and our hedonic price model, it is important to learn that properties around MRT stations remain very appealing to buyers in the local housing market. Therefore, it is fair to address that the global crisis has not yet jeopardize the prospect of transit oriented development in Kaohsiung.

Additionally, Tables 6, 7 and 8 show that the distance-to-MRT-station effects are nearly doubled for properties beyond 1 km or 1.6 km compared with properties within 1 km or 1.6 km. And the dummy variable of within 500 meters to MRT station does not have significant effect on property prices. This is somewhat tricky with the facts shown in Table 5. Perhaps the effect of KMRT on

property prices at the current stage has yet to be verified due to low patronage of the transit system. The prospective of KMRT, however, would be dependent on the future patronage brought by new TOD projects. It is no surprise that the hedonic price model exhibits significant effects of transit accessibility on property prices. In fact, it is the second most significant factors in the category of accessibility attributes. For residential properties, the elasticity of distance to CBD is about 13% to 29%, while the elasticity of distance to a MRT station ranges from 3% to 7%. As for commercial properties, the elasticity of distance to CBD is between 11% and 13% while the elasticity of distance to a MRT station ranges from 9% to 11%.

Although global financial crisis has minor effects on the local housing market, as suggested by the Housing Value Index and our hedonic price model, it is important to learn that properties around MRT stations remain very appealing to buyers in the local housing market. Therefore, it is fair to address that the global crisis has not yet jeopardize the prospect of transit oriented development in Kaohsiung.

Additionally, Tables 6, 7 and 8 show that the distance-to-MRT-station effects are nearly doubled for properties beyond 1 km or 1.6 km compared with properties within 1 km or 1.6 km. And the dummy variable of within 500 meters to MRT station does not have significant effect on property prices. This is somewhat tricky with the facts shown in Table 5. Perhaps the effect of KMRT on property prices at the current stage has yet to be verified due to low patronage of the transit system. The prospective of KMRT, however, would be dependent on the future patronage brought by new TOD projects.

## **5 Final Remarks**

In this research, we know a lot of things. In Taipei, the good things are a plenty of successful cases of TOD( including shopping mall, commercial area, and housing, etc united developments )and the MRT benefits lead to an increase in prices of nearby housing. In Kaohsiung, the good things is KMRT, the first MRT built with the BOT mode in Taiwan, and B(building) is the successful

example. It also has more public arts inside the stations, and they can serve as the example of future station designs. But both of Taipei and Kaohsiung have a lot of bad things. In Taipei, it had needed to pass longer construction period, has more impact on surrounding traffic And after the global financial crisis, it more influences the prices of housing that is far from the station. It has the same situation in Kaohsiung. In Kaohsiung, it has a lot of ugly things. By way of BOT, it now faces the problem of financial sustainability. Due to the low passenger volume, surrounding lands with TOD concepts cannot be developed. Another traffic structure, Kaohsiung Light Rail, which is planned to be built with the BOT mode, experience the predicament of a lack of investors. Other light rail plans in the country are declined by the central government.
